Printing House Project

Various publications such as books, posters, newspapers, and others are printed at a printing house.

Each publication is determined by title, unique identifier, publishing date, number of pages and size of the sheet of paper (A1, A2, A3, A4, A5). The unique identifier cannot be changed after the object of type publication is created. The price of the paper depends on its size.

The expenses for the paper are calculated by using the number of sheets of paper used for printing the publication and the price per sheet.

The income of the printing house comes from the printed publications. There is a price to print one publication.

For all the printing houses, there is the same profit tax percentage. Example: in Bulgaria this percentage is 10%. This tax has to be paid, based on the profit of the printing house.

Implement the following functionalities into the printing house project:

1. Make orders for printing publications. Each order has a publication and a given number of copies printed.
2. Calculate the expenses of the printing house, based on the paper needed to print the publications.
3. Calculate the income of the printing house, based on the printed publications.
4. Calculate the profit of the printing house.
5. Calculate the net profit of the printing house. Net profit is calculated after the tax is subtracted from the profit.
